User's Manual

10KV Digital High Voltage Insulation Tester

Model 380385
Introduction

Congratulations on your purchase of the Extech High Voltage Insulation Tester. This device has four pre-set voltage test ranges (up to 10kV) and measures insulation resistance to 500GΩ. Other voltage test values can be selected using the ±500V step buttons. This professional meter, with proper care, will provide years of safe reliable service.

Safety

1. Circuits under test must be de-energized and isolated before connections are made.
2. Circuit connections must not be touched during a test.
3. After insulation tests, capacitors must be discharged.
4. Test leads (including alligator clips) must be in good working order, clean and without broken or cracked insulation.
5. When servicing, use only specified replacement parts.
6. Environmental conditions:
   - Indoor use only; Installation category III 300V
   - Pollution degree 2
   - Altitude up to 2000 meters
   - Relative Humidity 80% max.; Temperature 0 to 40°C

International Safety Symbols

⚠️ Caution, refer to this manual before using this meter
⚠️ Dangerous Voltages; risk of electric shock
☐ Meter is protected throughout by double or reinforced insulation

Maintenance

Battery Replacement

When ‘REPLACE BATTERY’ appears on the display, replace the eight 1.5V ‘C’ batteries.

1. Ensure that the meter is powered down and that the test leads are not connected
2. Close the instrument cover and turn the instrument upside down
3. Remove the screw located on the bottom of the meter
4. Remove the battery compartment cover
5. Replace the eight batteries ensuring proper polarity
6. Affix the rear cover and secure the rear screw

Cleaning

Periodically wipe the case with a dry cloth. Do not use solvents or abrasives to clean this instrument.
### Specifications

#### General specifications

<table>

</table>

Note: Voltage Regulation is +20% -5% unless current limited.
**Meter Description**

1. Test lead jacks
2. Dot Matrix Display
3. Keypad
4. Battery compartment (on bottom)
5. Test lead compartment latch

**Preparation**

**Warning:** Ensure that the circuit under test does not include devices or components that can be damaged by 10KVDC; such devices include power factor correction capacitors, low voltage mineral insulated cables, electronic light dimmers, ballasts and starters for fluorescent lamps.

Connecting the Test Leads to the meter

The Black (Earth), Red (Line), and Green (Guard) test leads connect to the meter directly above the dot matrix display (the meter jacks are color coded). NOTE: The Green (Guard) lead is attached to the Red lead and should be used (refer to applications section next).

Connecting the Test Leads to the device under test

The Black (Earth) lead is connected to the conductive material. The Red (Line) and Green (Guard) leads are connected to insulating, sheathing, and covering material as shown in the following applications section.
**Operation**

**Powering the meter**

Press the **ON** button to turn the unit on. Press the **OFF** button to turn the unit off.

**Insulation Resistance Measurements**

**Warning:** The circuit under test must be completely de-energized and isolated before making test connections.

1. After turning the unit on, the display will prompt the user to select a test voltage (diagram at right).

2. Select the test voltage by pressing one of the preset voltage buttons (1KV, 2.5KV, 5KV, 10KV) or by pressing the Voltage Adjust buttons (500+, 500-) to step through the available test voltages in 500V steps.

3. The resistance range for the selected voltage is indicated on the dot matrix display as shown above.

4. Press the **TEST START / STOP** button again.

5. The display will prompt the user to connect the leads. Press the **TEST START/STOP** button to start testing.

6. The elapsed test time appears on the upper line (right hand side) of the display. The resistance reading is shown on the upper left hand side of the display. The lower line shows the test voltage in bargraph format (see diagram at right).

7. The HOLD icon will appear in place of the bargraph when the test is complete and the voltage has been discharged.

**WARNING:** DO NOT REMOVE THE TEST LEADS BEFORE THE HOLD DISPLAY APPEARS.

8. The meter automatically discharges the system at the end of the test.

9. The meter automatically powers down after 5 minutes.

**The Enersave™ Mode**

Enersave™ mode conserves battery life by performing a relatively short test (10 seconds). The Enersave™ mode is the default test mode. To bypass this mode and run a longer test (100 seconds max), press and hold the **TEST** button for 3 seconds when starting a test.

**Bargraph Voltage Display**

The bargraph represents the voltage present on the test leads as it rises, soaks, and decays. The bargraph appears on the lower left of the dot matrix display during a test.

**Automatic Under/Over Range Resistance Detect**

If the display shows the message “LOW Ω”, the test should be interrupted immediately by pressing the **TEST** button. This message indicates that the insulation under test has broken down and the meter is trying to inject a high potential onto a short circuit. If "HIGH" appears, it is likely that the test configuration is open. Check the test set-up then test again.

**Elapsed Timer**

The test duration is indicated on the display. This is particularly useful in determining whether an insulating material under test will break down in a given amount of time.
Manual Test STOP

To stop a test in progress, press the TEST button. The test will immediately end and the system will automatically discharge.

Automatic Test STOP

When in the default Enersave™ mode, the test automatically stops after approx. 10 seconds. The test automatically stops after approx. 100 seconds if the meter is not in the Enersave™ mode.

Live Circuit Warning

If the test leads are connected to a live circuit (approx. 500V), a warning beeper will sound and the meter will display “Live Warning…Circuit Live…”. In this case, correct the problem and retest.

Automatic Discharge

At the end of a test, the meter automatically discharges the high voltage. The automatic discharge status is reflected on the display. During discharge the beeper will sound and, when completely discharged, the HOLD icon appears on the display.

Applications

Measuring Power Tools and Small Appliances

For small appliances, connect the Black (EARTH) lead to conductors and the Red (LINE) lead to insulating material.

For single or double insulated power tools, one lead should be connected to the device’s chuck, blade, etc. and the other lead to one of the AC power cord conductors (test both conductors in turn). Refer to the power tool application diagram below.

Testing Motors

AC Motors

Disconnect the motor from the line by:

a. Disconnecting the wires from the motor terminals or
b. Opening the main switch

If the main switch is opened, and the motor also has a motor-starter, then the starter must be held in the ON position. With the main switch opened, the measured resistance will include the resistance of the motor wire and all other components between the motor and the main switch. If a weakness is indicated, the motor and other components should be checked individually. If the motor is disconnected at the motor terminals, connect the RED lead to the grounded motor housing and the BLACK lead to one of the motor leads.
DC Motors
1. Disconnect the motor from the line.
2. To test the brush rigging, field coils and armature, connect the RED lead to the grounded motor housing and the BLACK lead to the brush on the commutator.
3. If the resistance measurement indicates a weakness, raise the brushes off of the commutator and separately test the armature, field coils and brush rigging by connecting one lead to each individually, leaving the other connected to the grounded motor housing. This also applies to DC Generators.

Testing Single Conductor Cables
1. Completely disconnect the cable under test from its source and destination.
2. Connect the test leads to the cable as shown at right.

Testing Multi Conductor Cables
1. Completely disconnect the cable under test from its source and destination.
2. Refer to the diagrams below for three possible tests.

Transformer Testing
Transformer tests are performed with the transformer completely disconnected from the line and the load. Note that the case ground should not be removed.

The five tests listed below will completely test a single-phase transformer. Note that at least 1 minute should be allowed between each test.

1. High voltage winding to low voltage winding and ground
2. Low voltage winding to high voltage winding and ground
3. High voltage winding to low voltage winding (pictured at right)
4. High voltage winding to ground
5. Low voltage winding to ground
